### Introduction

Politicians have on average much higher levels of education than citizens (Gaxie and Godmer, 2007; Bovens and Wille, 2017; Gerring et al., 2019). A long tradition sees the overrepresentation of highly educated citizens in office as desirable and justified on the basis that education is a sign of competence (Dal Bo and Finan, 2018): highly educated individuals are considered as better able to understand politics, as better managers, as having more authority on others, and as being more committed to the well-being of their communities than the less educated. Seconding this elitist view, numerous studies use the education of politicians as a proxy of their unobserved “quality” (e.g. Galasso and Nannicini, 2011; Gagliarducci and Nannicini, 2013; Baltrunaite et al., 2014; Artiles, Kleine-Rueschkamp and Leon-Ciliotta, 2018; Becher and Menendez, 2019). In spite of the long-standing trust in the higher ability of educated political elites and the pronounced and pervasive educational bias in the composition of governments and legislatures, evidence about the consequences of having highly educated politicians on policy outcomes is scarce and conflicting. Some studies have argued that educated political leaders produce positive outcomes such as better economic performance (Besley, Montalvo and Reynal-Querol, 2011; Congleton and Zhang, 2013) or an increase in the provision of public goods (Martinez-Bravo, 2017). Other studies find that the education of politicians is irrelevant for policy outcomes (Freier and Thomasius, 2015; Carnes and Lupu, 2017), or find mixed evidence (Lahoti and Sahoo, 2020).

This chapter studies if the education level of politicians in government affects fiscal policies and performance. While previous empirical research either views education as a sign of the quality of politicians or finds that highly and less educated politicians implement similar policies, our research introduces a third possibility, which is that governments led by more educated politicians implement more conservative fiscal policies.

To study this question, we present detailed analyses based on data from Spanish municipalities between 2003 and 2011. We construct an original dataset with information about the gender, age and education of all mayoral candidates to local elections, and match it to local policy outcomes, including fine-grained information about budget items, tax rates, and spending in several policy areas. To address endogeneity concerns, we follow previous research that applies regression discontinuity designs to study the effects of partisanship and the characteristics of politicians on various outcomes (e.g. Ferreira and Gyourko, 2009; Gerber and Hopkins, 2011). Our identification strategy, which is tailored to the PR system

employed in Spanish municipal elections, exploits close races between mayoral candidates with and without a university degree to examine if performance and fiscal policy differed in municipalities where a candidate with a university degree just won or just lost an election.

The RD estimates suggest that when highly-educated politicians closely win an election, municipalities do not have better outcomes in respect to unemployment, population growth, primary deficit, or a close match between projected and realized spending, nor are these governments more likely to be reelected. Our analysis of budget items and spending categories provides evidence that, on average, less educated mayors choose higher levels of capital spending, and increase spending in basic infrastructure projects. We also find that the positive effect of electing left-wing governments on capital spending is reduced when the mayors of left-wing parties have a university degree. Overall, our results suggest that educated and non-educated politicians differ on preferences rather than on ability.

This chapter complements recent work on the social class background of politicians (Carnes, 2013; Carnes and Lupu, 2015; Pontusson, 2015; O’Grady, 2019). Our study joins others that claim that a lack of descriptive representation by socio-economic status does not produce obvious benefits in terms of better government performance. Our findings suggest that the over-representation of highly educated citizens in office can introduce a conservative bias in public policy.

## Theory

Our work is motivated by studies which demonstrate that public policies are not determined by the median voter and political institutions alone, but also by the identity of political leaders (Pande, 2003; Chattopadhyay and Duflo, 2004; Jones and Olken, 2005; Bhalotra and Clots-Figueras, 2014). This claim has wide-ranging implications. Above all, when the composition of governments and legislatures differs from the composition of the population, policies will deviate from the counter-factual situation in which politicians resemble the population. Policy bias will, in all likelihood, favor the over-represented groups. The most important respect in which politicians stand out in advanced industrial democracies is their privileged socio-economic background. Whereas the under-representation of women and minorities has improved markedly over time, it has only worsened for workers, the less educated, and low-income citizens (Gaxie and Godmer, 2007; Carnes, 2013; Bovens and Wille, 2017; O’Grady, 2019).

Different dimensions of socio-economic advantage such as income, occupation and education are highly correlated, but education has differential features that justify a separate assessment.<sup>1</sup> Highly educated governments have been defended based on the purported higher ability of their members. However, education is not only the result of higher ability and a vehicle of social mobility, but also a mechanism for the reproduction of inequality (Lee and Seshadri, N.d.). Having parents of a higher socio-economic and educational background predicts educational attainment and ultimately income, beyond differences in ability.<sup>2</sup> Education can affect the preferences of citizens through a variety of channels,

---

<sup>1</sup> As Pontusson (2015) points out, little is known about the distinct effect of income, occupational background, and education on the preferences and behavior of politicians and this paper cannot establish if these effects differ. We deem education as relevant on its own right. Given that educational credentials are required for most white-collar occupations, we also see it as implausible that the effects of education and social class differ dramatically. As we discuss in the conclusions, the content of education and the occupations it gives access to may also be influential and further analyses are needed to address this question.

<sup>2</sup> In a related study about the inter-generational transmission of inequality in Spain, (Bernardi and Ares, 2017) find that the offspring of highly educated parents such as university professors have higher incomes, even controlling for the offspring’s education level between competence and representation Gulzar (for a discussion about this trade-off see 2021).

some of which are separate from income or occupation (as we discuss in detail below). The distinctive features of education justify the need for a careful analysis of both valence and positional outcomes that could reveal trade-offs.

### **Previous studies: Better performance or no effects?**

A first strand of studies finds that highly educated politicians are more competent. Besley, Montalvo and Reynal-Querol (2011) exploit the death of leaders due to natural causes to identify the effects of their education on economic growth and find that the departure of highly educated leaders from office reduces economic growth. Martinez- Bravo (2017) exploits a large education program in Indonesia and finds that highly educated village heads govern more efficiently and deliver more public goods than less educated village heads. Lahoti and Sahoo (2020) find that educated politicians produce better educational outcomes in developed states in India, but not in less developed states.

There are several reasons why highly educated politicians may perform better. Educated people score higher on cognitive and non-cognitive traits which predict job performance, including crystallized and fluid intelligence and personality traits such as openness to experience, conscientiousness, and emotional stability (Heckman and Kautz, 2012). Skills acquired through formal training or job experience, such as accounting skills, team management, or legal knowledge, can be transferred to government tasks. The correlation of education and desirable abilities and traits may be due to a mixture of self-selection of people with these traits to pursue post-secondary education and to formal education enhancing abilities such as mathematical, verbal skills or grit. Whatever the direction of causality, if this positive correlation holds among politicians, we should expect highly educated politicians to deliver better outcomes than less educated politicians on indicators of economic performance.

The dominant view that highly educated politicians perform better than less educated politicians has been challenged empirically by Carnes and Lupu (2017) who reanalyze Besley, Montalvo and Reynal-Querol (2011) data using a broader set of outcome measures and fail to find a positive effect on performance. They confirm these null results using further evidence from close elections in US congressional elections and mayoral elections in Brazil. Similarly, Freier and Thomasius (2015) do not find an effect of education on local spending and debt in German municipalities.

Two reasons stand out that may explain these null effects. Politicians may simply not be able to influence policy outcomes much, perhaps because other factors are more important or because governments have little power. The lack of effect of education on performance may also be due to self-selection. As in the case of female politicians (Anzia and Berry, 2011), less educated citizens may be less likely to run and to obtain supports, holding quality equal. As a consequence, only the most exceptional less educated citizens will run in elections and win office. Adverse selection may operate among highly educated citizens. If the salaries of politicians are lower than the salaries of highly educated workers in the private sector, perhaps only those with a low ability among the highly educated choose to run. As a result of both processes, even if there is a positive correlation between education and ability in the population, this correlation could be weakened among politicians. The prediction of this argument is that the education of politicians should not affect governmental performance.

### **Education and economic preferences**

A third possibility is that educated politicians have different preferences and implement more fiscally conservative policies than less educated politicians. The more general theoretical argument, in line with citizen-candidate models of representation Besley (2006), is that the individual characteristics of politicians are informative about their preferences and shape their actions in office. The main testable hypothesis is that the identity of politicians predicts public policies, a general claim that has been applied to multiple individual characteristics (Burden, 2007).

Education can shape preferences through multiple channels, some common to other socio-economic characteristics and others specific to education. The first is the income channel: Educated people have higher incomes and income potential and hence different material interests. As an illustration of this well-known correlation for the Spanish case, according to the yearly Survey on Life Conditions conducted by the National Statistics Institute, citizens with university degrees had incomes more than twice as high, on average, as citizens with lower secondary education. Given the progressive structure of the tax system, this means that more educated citizens pay relatively more taxes than less educated citizens. Higher incomes also give educated citizens better access to privately provided health care, education and other services. Because they pay more in and get less out, they should have a preference for a smaller size of the state.

A slightly different material interest channel relates to the risk of unemployment. Less educated citizens face much higher economic risks (Hacker, Rehm and Schlesinger, 2013) and hence are more reliant on social protection. In Spain in 2007, people aged between 25 and 64 who had primary education were twice as likely to be unemployed than people with university education. The unemployment rate was 9.9 and 4.8 respectively. In 2010, the gap was even larger at 28 and 10.5. As a consequence of both their different incomes and risk levels, citizens –and politicians– with low levels of education should prefer a larger and more generous state.

There are several non-material channels through which education can produce more fiscally conservative preferences, some of which are particularly relevant in the case of politicians. First, education strongly affects the composition of people’s networks. Educated politicians will have fewer acquaintances in their networks in situations of unemployment and economic hardship, which should limit the salience of these issues. Vicarious exposure to economic hardship also affects perceptions about the deserving-ness of those affected and hence views on economic issues (Newman, 2013). A second reason why the educational composition of the networks of policy-makers is important is that less educated politicians should be more likely than highly educated politicians to be approached and lobbied by less educated citizens (because networks facilitate access). Note that this “access channel” does not operate through the preferences of politicians.

Independently of income, risk, and networks, educated politicians may have more conservative economic views because of their different socialization experiences in educational environments during their formative years. Independently of their background, educated politicians have been socialized in secondary and university environments, in which peers of privileged backgrounds abound. Experiences lived in privileged educational environments lead to the development of more conservative worldviews (Mendelberg, McCabe and Thal, 2016). In addition, educated citizens (either because of self-serving biases or because of exposure to the rigors and delayed gratification of schooling) may be more likely to endorse “just-world” beliefs and view inequalities as a result of meritocracy.

Empirically, education has been repeatedly found to predict preferences for economic and welfare policies among citizens. For instance, education is associated with less support for redistribution (Rehm, 2009) and social policies (Häusermann, Kurer and Schwander, 2016), more support for

economic globalization (Naoi, 2020), and opposition to protectionism (Hainmueller and Hiscox, 2006).<sup>3</sup> Also in Spain, education is associated with right-wing economic policies (Calzada and Del Pino, 2008).

We expect governments led by educated politicians to reduce the size of the state and use less interventionist and expansionary policies. The most relevant evidence supporting this expectation is provided by Carnes and Lupu (2015) who find that politicians with a working class background (which correlates very strongly with education) sponsor more "leftist" bills and have more leftist ideal points. These authors look at legislative activity and do not examine if the class of legislators ultimately affects policy outcomes. There is some indirect evidence that the educational background of decision-makers may affect the fiscal conservatism of the policies they adopt and the economic results they obtain. For instance, the education and professional background of central bankers affect monetary policies (Gohlmann and Vaubel, 2007; Adolph, 2013), as well as the resulting inflation and unemployment rates. These studies focus mostly on the type of university education achieved and do not examine elected politicians but high-level economic decision-makers. Dreher et al. (2009) examines the effect of the educational level and background of the heads of governments on the adoption of market-liberalizing reforms and finds that, in some specifications, educated heads of government are more likely to initiate such reforms. Our main hypothesis is thus that governments led by educated politicians implement more conservative fiscal policies.

Testing this hypothesis poses an important identification challenge because of the correlation between the education of the population, of politicians, and of municipal- and party-level characteristics. Our research attempts to disentangle the effect of educated governments using a quasi-experimental regression discontinuity design focusing on municipal elections in Spain.

### **Institutional background and data**

To examine the impact of education on government performance and fiscal policies it is crucial to understand the constraints faced by politicians in a particular context. As our empirical analyses are focused on Spanish local governments, in this section we describe their main features with emphasis on how the members of the city council are elected, the structure of local public finances, and the capacity of local politicians to influence fiscal policy. We also discuss the data used to test the hypotheses and the construction of our main variables.

### **Spanish local elections**

Spain has a decentralized political system with elected governments at the national, regional and municipal level. Since 1979, citizens elect local councils every four years in about 8,000 municipalities, but our analysis only includes municipalities with more than 1000 inhabitants.<sup>4</sup> Depending on their size,

---

<sup>3</sup> We do not provide a full overview of the vast empirical literature on education and political preferences here, but note two important points. First, the correlation between education and self-placement in the left-right spectrum varies across countries and is often small. This in part reflects the multidimensionality of ideology, which includes social issues such as abortion on which educated citizens are more left-wing. Second, there is some disagreement in the literature about the relative importance of education vis a vis other socio-economic characteristics. Horse races between competing variables are misguided in this case because alternative measures of socio-economic position such as income and occupation are themselves partly affected by education, which is temporarily previous to these variables.

<sup>4</sup> Data on several key variables is missing in municipalities with less than 1000 inhabitants.

municipalities elect 9 councilors or more using a closed party list proportional representation system (PR). In the first meeting, the local council elects a mayor, which is usually the first candidate of the party list with the most votes. The city council is the main decision-making body during the legislature and is responsible for approving the budget, tax codes, laws, regulations and zoning.

Spanish local governments have considerable influence on the well-being of citizens. By law, municipalities are required to provide a number of services such as waste collection, street cleaning, public lightning, sewerage, and roads pavement. In addition, larger municipalities must provide other services depending on their size. They can also provide additional goods and services on a voluntary basis. Municipalities manage about 14 percent of total public expenditure. This figure is similar to countries like Belgium, Austria, Portugal or Germany. They are, however, an important employer at 647.000 employees in 2015 according to the Ministry of Territorial Policy and Administration. Section S1.1 in the supporting information complements this description with further details about Spanish electoral law.

### **Local public finances**

The revenues of local governments come from own resources and transfers from other levels of government. Municipalities can levy a number of taxes and fees, and receive fixed shares of the revenues of indirect taxes and the income tax. In 2009, taxes and fees amounted to 43% of total revenues. Current transfers amounted to 27% of revenues, with the main grant being the revenue-sharing grant transferred by the central government using a fixed formula based on population size and other parameters. Most other grants, including European grants, are earmarked for specific purposes. Regarding expenditures, the bulk of local expenditure (84%) was approximately equally distributed between three categories: personnel (29.4%), current goods and services (28.3%) and real investment (26.9%). The empirical analyses focus mostly on the largest categories.

As in other countries, the discretion that local governments have over expenditures is greater than their capacity to raise revenues. Municipalities have a limited capacity to issue debt and can mostly influence revenues by raising or reducing local taxes and by attracting grants.<sup>5</sup>

### **Data: Politicians, performance and fiscal policy**

Our analyses draw on an original dataset with individual-level information about the characteristics of local councilors elected in Spain in 2003 and 2007. Municipalities collect the data and send it to the Spanish Ministry of Finance (Ministerio de Hacienda y Administraciones Publicas), which granted access to the researchers. The dataset details the education, gender, age, and occupation of local council members.<sup>6</sup> Our dataset contains information on around 1,200 municipalities with more than 1000 inhabitants for two terms of office (2003-2007 and 2007-2010). On average, the education of local councilors in our sample is 13 years with a standard deviation of 2.42. The level of education of mayors

---

<sup>5</sup> Specifically, they can set tax rates for some direct local taxes, with the most important being the property tax. In contrast to formula-based current transfers, municipalities can attract capital transfers, which are largely distributed at the discretion of the granter government. Hence, local politicians can mostly influence total revenues by setting taxes and fees, and attracting revenues from capital transfers.

<sup>6</sup> Unfortunately, the occupational data contains many missing values and we do not use it in the main analyses. We provide some descriptive analyses in the supporting information. More educated politicians typically have backgrounds in professional occupations such as law, health or education. Less educated politicians often have industrial or agricultural occupations, hence supporting our claim that education is associated with different material interests and socialization experiences.

is slightly higher at 14 years. This is significantly higher than the education of the Spanish adult population, which according to the census is less than 10 years on average.<sup>7</sup>

We complement the dataset about the individual characteristics of local politicians with extensive municipal-level information on electoral results, performance outcomes, and fiscal data. The share of votes for the different parties are obtained from the Spanish Ministry of Home Affairs (Ministerio del Interior), which also provides data about population size, the number of registered voters, and the party of the mayor. We collect a variety of performance indicators to test if educated mayors perform better, 5In 2012, a new law was passed which forced municipalities to balance budgets and curtailed the ability of governments to influence outcomes through fiscal policy. Moreover, the categories of reported fiscal data changed, making longer series not comparable. Hence, we limit our analyses to the pre-reform period.

We view unemployment as an important indicator of economic performance. Although unemployment is not directly affected by municipalities, they can create jobs through public hiring or stimulating the local economy. Another performance indicator is population growth, which may be a proxy for the attractiveness of the municipality. We use deficit per capita as an additional measure of performance, although we acknowledge that this is debatable given that municipalities could use deficit to counter-act economic cycles. Our next indicator of quality is the share of the vote for the incumbent party at the next election. Finally, we calculate the deviation between the budget approved for a given year (forecasted) and the actual amount spent in that year. This measures the ability of governments to administer their budgets as they intend to.

For our analyses about the effect of education on fiscal policies, we gather data from the annual budgets (liquidaciones) provided by Spanish municipalities and collected by the Ministry of Finance (Ministerio de Hacienda y Administraciones Publicas). We focus on the most important categories, these are total non-financial revenues and expenditures per capita and their main categories: capital transfers, current transfers, taxes and fees, capital spending, and spending on current goods and personnel.

Each observation in our dataset represents one municipality during a mayoral term. Compared to the original sample, our final sample is reduced significantly for several reasons. First, we exclude all municipalities with less than 1,000 inhabitants because, as mentioned, many variables are not available for these municipalities. We also exclude places where the mayor is not amongst winner and runner-up (2%) and where both the winner and runner-up have a university degree.

### **Empirical strategy**

As educated politicians are not randomly assigned to municipalities, many time-invariant and time-varying unobservable factors can be correlated with both the education of mayors and economic outcomes. For example, changes in voter preferences or in the composition of the population may influence both demand for different fiscal policies and for more educated politicians. Thus, empirical approaches such as fixed-effects models are unable to establish causal links.<sup>9</sup> To overcome concerns about endogeneity, we employ a Regression Discontinuity (RD) design to estimate the effect of the education of mayors on government performance and fiscal policies in Spanish municipalities. The

---

<sup>7</sup> The supporting information describes the evolution of the average years of education of politicians and the population aged 25 or older since 1979. Over the whole period, politicians are consistently more educated than the population, and the gap is stable over time.

intuition of the RD design is that municipalities where the party with the most educated candidate win are very similar to municipalities where the most educated candidate lost (i.e. the latter are a good control group for the former). At the limit, the outcomes of these elections can be treated as random, which allows obtaining quasi-experimental estimates of the effects of interest.

We focus on municipalities in which the two parties with the highest and second highest number of seats (usually the main government and opposition parties) vary in the university attainment of their leading candidates. That is, we include only municipalities where one of the two main candidates had a university degree, while the other did not have it. To construct our forcing variable, we calculate the vote margin ( $v_{it}$ ) of the party with a university educated candidate as the percentage of votes this party needs to win (lose) to become the winner (the runner-up) in terms of seats.

The RD approach has been mostly applied to majoritarian electoral systems such as the U.S. By contrast, Spain has a PR system in which the party that wins an election may not be in government if it has less than 50% of seats and other parties can form a coalition with a majority of seats. In about 94% of municipalities in our sample the mayor belongs to the winning party. We follow Curto-Grau, Sole-Olle and Sorribas-Navarro (2018) and Folke (2014) and implement a fuzzy set regression discontinuity design adapted to PR systems.

More formally, we estimate the following equations:

$$u_{it} = \beta_1 d_{it} + f(v_{it}) + \eta_t + \epsilon_{it} \quad (1)$$

$$y_{it} = \alpha_1 u_{it} + g(v_{it}) + \eta_t + u_{it} \quad (2)$$

where  $u_{it}$  equals 1 if the mayor in municipality  $i$  at time  $t$  has a university degree. The variable  $y_{it}$  refers to the outcomes of interest in fiscal year  $t$ . Our forcing variable —the margin of victory of the candidate with a university degree— is represented by  $v_{it}$  and we construct a dummy variable  $d_{it}$  that equals 1 if this margin is positive and 0 if it is negative. The margin of victory is based on the outcomes of the most recent election.<sup>8</sup> The function  $f(v_{it})$  is a function of the forcing variable fitted on each side of the threshold.

We report estimates using local linear regressions and a data-driven optimal bandwidth as per Calonico, Cattaneo and Titiunik (2014a,b). All specifications report cluster standard errors at the municipality level and include time and region fixed effects as Spain presents significant regional heterogeneity in political and economic characteristics. The coefficient of interest,  $\alpha_1$ , is the Local Average Treatment Effect (LATE), which is a robust estimate of the causal effect for observations near the threshold.

### Validation of the RD strategy

The validity of the RD estimates relies on the assumption that the forcing variable, in this case the margin of victory of the party with a university educated candidate, is not manipulated by political parties. When the margin of victory is very narrow, winning or losing the election should be a random event not influenced by electoral fraud. To check this assumption, we use the manipulation test proposed by Calonico, Cattaneo and Titiunik (2015). Figure 1 shows that, at the threshold, the density of the forcing

---

<sup>8</sup> Recall that the budget of a specific fiscal year,  $t$ , is approved in  $t-1$ . This means that officials elected in 2003 are responsible for the budgets of fiscal years 2004, 2005, 2006 and 2007 and those elected in 2007 set the budgets of fiscal years 2008, 2009, 2010, and 2011.

variable is not discontinuous. This means that when candidates of different education levels compete in a close election, neither the more nor the less educated candidate have a significantly higher likelihood of winning.

Figure 1: Continuity of the forcing variable

Notes: Density plot of the forcing variable computed with rddensity Stata program.

In Table 1, we test for the presence of discontinuities for key political and socioeconomic variables. We find discontinuities in the mayors' gender. This reflects that female candidates tend to be better-educated than male candidates. To address concerns that difference in the gender of mayors might affect our results, we control for this variable at both sides of the threshold in the main analyses. We also find a discontinuity in regards to the percentage of retired citizens living in the municipality, and control for this in the analyses.

Table 1: Discontinuities in political and socioeconomic covariates

Coef.	SE
Female mayor	0.273* (0.111)
Mayor's age	4.624 (2.695)
Party alignment with regional government	0.176 (0.152)
Party alignment with central government	0.208 (0.157)
Party alignment with provincial government	0.085 (0.153)
Left-wing mayor	0.182 (0.152)
Majority government	0.082 (0.159)
Mayor is manager	-0.152 (0.122)
Turnout	-0.020 (0.031)
Initial debt per capita	-24.99 (15.66)
Population	7.338 (4.963)
Density	731.0 (474.7)
% Population <14	1.068 (0.995)
% Population >65	-4.716* (2.107)
Income	-0.063 (0.0474)
Weight of tertiary sector	4.074 (4.355)
% Foreigners (EU)	0.0773 (0.658)
% Foreigners (non-EU)	-0.955 (0.118)
% College education	-1.150 (2.631)

## Results

In the empirical analyses, we first examine if educated politicians perform better in office using a variety of indicators. After showing that this is not the case, we present the main empirical analyses which test the hypothesis that the educated governments choose more conservative policies with extensive data on local finances.

### Education and government performance

This section provides evidence about the causal effect of education on several performance indicators. To start, in column 1 of Table 2, we regress unemployment rates on the level of education of the government, and find that electing mayors with a university degree leads to an increase of 0.36 percentage points in local unemployment rates, a 4% increase in unemployment. As discussed above, given the characteristics of the Spanish economy, we regard unemployment as a particularly important indicator of performance. Educated politicians perform worse in this respect.

We also test whether the government's education affects population growth, which

can signal quality if people are attracted to municipalities with a better provision of public goods and services. In column 2 of Table 2, we present the estimates of regressing municipal population growth from the start to the end the 4-year electoral term (hence the smaller number of observations) on the average education level of the government and find no statistically significant effect. Balanced budgets can also be regarded as indicators of good government performance, although deficit and surplus can also be a counter-cyclical fiscal policy used by governments. In column 3, we show the results of regressing the level of primary deficit per capita on the level of education. There is no evidence that more educated governments run smaller deficits.

Another indicator of government performance is the vote share of the incumbent in the next election. Voters should reward good governments such that the vote share of a well-performing incumbent party should be higher than the average incumbent. We test this hypothesis in column 4 and find that more educated politicians do not perform better. Lastly, we examine whether more educated governments are better at forecasting the spending needs of the municipality and able to stick to their own proposed budget. We construct a variable that measures the percentage difference between the actual expenditures and their initial forecast approved by the local government at the start of the fiscal year. The estimates in column 5 show that the education of the government has no statistically significant effect on this indicator.<sup>11</sup>

Table 2: Effect of mayors with university degrees on performance outcomes

	Unemployment rate	Population growth	Incumbent vote at t+1	Deviation from budget	Primary exp.deficit pc
Education	0.357 (0.194)*	-0.215 (0.634)	-0.646 (1.003)	-1.148 (1.296)	2.163 (5.526)
Bandwidth	0.185	0.190	0.158	0.168	0.173
Mean outcome	8.29	4.99	-1.40	1.38	-5.47

Notes: Standard errors clustered at the municipality level in parentheses, \*\*\* $p < 0.01$ , \*\* $p < 0.05$ , \* $p < 0.1$ . All RD estimates are obtained by local linear regression and optimal bandwidth as per Calonico, Cattaneo and Titiunik (2014a). All specifications include time and region fixed effects. Unemployment growth = percentage change in unemployed people (as a share of working-age population) between the first and last year of the legislature. Primary deficit, and total expenditures (columns 3 and 4) are

expressed in euros per capita. Deviation from exp. budget = percentage difference between the actual expenditure budget and its initial forecast approved by the local government.

<sup>11</sup>The effect on the difference between the revenue budget and its forecast is also statistically insignificant.

### The effect of education on fiscal policies

This section analyses if the education of politicians affects the choice of fiscal policies. Table 3 presents LATE estimates using key spending and revenue categories of the local budget as dependent variables. We focus on the largest budget chapters as discussed in section 3.2 on local public finances. Except for current revenues, local governments have considerable discretion to influence these chapters.

The results indicate that more educated mayors reduce expenditures and revenues per capita. Mayors with university degrees decrease total spending per capita by 36 euros (3.8% lower expenditures) and total revenues per capita by 32 euros (3.3% less funds). The negative effect of mayors' education on local public spending is driven by lower capital spending, while the effect on current spending (expenditures on both personnel and current goods) is statistically insignificant. We find that electing a university educated mayor decreases capital expenditures by 35 euros per capita (11% lower investment, on average). With regards to revenues, only capital transfers are affected by the education of mayors. University educated mayors decrease of 13 euros per capita (7% relative to the mean transfers). Given that capital transfers are used to finance public investment, the negative effect we observe can be attributed to lower capital spending. Although we cannot demonstrate that increased investment reduces unemployment, this is a plausible possibility. By contrast, our results suggest that it is unlikely that less educated mayors reduce unemployment by increased public hiring, a classical clientelistic strategy.

Table 3: Effect of mayors with university degrees on fiscal outcomes

Variable	Coef.	SE	Mean outcome
Non-financial expenditures	-36.114	(12.493)***	949.98
Personnel spending	-5.57	(4.94)	290.48
Goods and services spending	-8.52	(5.24)	281.77
Capital spending	-15.71	(7.18)**	288.59
Non-financial revenues	-32.41	(11.67)***	965.24
Current transfers	-6.23	(5.18)	289.69
Capital transfers	-12.60	(5.41)**	180.86
Taxes and fees	-8.85	(8.94)	410.23

Notes: Standard errors clustered at the municipality level in parentheses, \*\*\* $p < 0.01$ , \*\* $p < 0.05$ , \* $p < 0.1$ . All RD estimates are obtained by local linear regression and optimal bandwidth as per Calonico, Cattaneo and Titiunik (2014a). All specifications include time and region fixed effects. The dependent variables are expressed in euros per capita and the figures represent averages over the 4-year term of office.

These analyses suggest that better educated governments are more fiscally conservative, in the sense that they prefer smaller governments than less educated politicians. Lower total revenues and expenditure are driven by the fact that educated governments invest less and receive lower capital transfers. To shed some light on the areas to which this increased investment may be going, the next section examines spending by "functional" area. This is also informative about the revealed policy priorities of politicians.

#### The effect of education on key revenue categories

Besides capital transfers, city councils can influence some other revenue categories, the most important being revenues from fees and direct taxes. In Table 4, we present the RD estimates of the effect of the education of governments on those categories. In contrast to capital transfers, we do not find any effect on the other revenue categories at conventional significance levels.

To investigate the influence of education on taxation, we narrow the analysis to the taxes on which city councils have most discretion: the urban and rural property tax. The coefficients are positive, but they are insignificant and the magnitudes are very small. Thus, it is unlikely that the education of governments influences tax revenues to a large extent.

Table 4: Effect of mayors with university degrees on key revenue categories and tax rates

	Coef.	SE	Bandw.	N	Mean outcome
Revenues from:					
Fees	8.587	(9.373)	0.13	1,016	177.57
Direct taxes	-19.258	(21.388)	0.17	1,262	250.63
Tax rates:					
Urban property tax	0.006	(0.008)	0.13	1,169	1.38
Rural property tax	0.009	(0.011)	0.16	1,208	0.65

Notes: Standard errors clustered at the municipality level in parentheses, \*\*\* $p < 0.01$ , \*\* $p < 0.05$ , \* $p < 0.1$ . All RD estimates are obtained by local linear regression and optimal bandwidth as per Calonico, Cattaneo and Titiunik (2014a). All specifications include time and region fixed effects.

The findings about taxes and fees are relevant because they once more disconfirm the claim that less educated governments have a lower quality. In section 5.2, we found that less educated governments spend more, but these analyses suggest that they are not incurring more deficit nor are they increasing fiscal pressure. Hence, their higher spending is not financed through strategies that could be detrimental in the long-term. Rather, it seems that less educated governments finance higher spending by attracting capital transfers from other administrations.

#### Effects on spending areas

Our dataset provides information about how total spending is distributed across policy areas. This functional data is rare and valuable, but much noisier than the data about types of spending presented above. First, many municipalities do not report this data, leading to a higher number of missing values. Second, the classification of budget items to policy areas is often subjective and the internal organization of areas in policy departments varies substantially across municipalities, leading to more measurement error.

In 2009, two out of eight investment items, production of public and social goods and production of economic goods absorbed 87.4% of local capital expenditures and 62% of total spending. The most important areas in budgetary terms are housing, community welfare (including waste and water management), culture, and basic infrastructure. By contrast, spending on areas such as health and education is low because municipalities only have residual powers on these policy areas.

Table 5 presents the findings regarding the effect of the education of mayors on total

expenditures (including capital spending and other types of spending) in the two main functional categories and their corresponding sub-categories. For each expenditure area and each year, we compute the share of total expenditures allocated to that function. Following previous work (Gerber and Hopkins, 2011) (e.g., Gerber and Hopkins 2011), we use this measure because it reflects policy preferences better than per capita spending. The results indicate that electing a mayor with a university degree decreases spending in basic infrastructures, transportation and agrarian infrastructures. These results are also important. Basic infrastructure and transportation projects may be one of the targets of the increased investment we detected in previous analyses. This again is consistent with our interpretation that less educated politicians adopt more Keynesian policies.

Table 5: Effect of governments' education on key areas

Expenditure by function	Coef.	SE	Mean outcome
Production of public and social goods	1.216	(0.746)	47.02
Health	0.189	(0.245)	1.68
Education	0.209	(0.178)	3.87
Housing and urban planning	0.558	(0.532)	14.14
Community welfare	0.034	(0.313)	10.87
Culture	0.218	(0.314)	13.00
Other social and community services	-0.081	(0.270)	3.63
Production of economic goods	-1.008	(0.497)**	10.96
Basic infrastructure and transportation	-0.890	(0.481)*	9.91
Communications	0.019	(0.018)	0.13
Agrarian infrastructure	-0.115	(0.060)*	0.63
Research	0.019	(0.014)	0.034
Basic information and statistics	-0.031	(0.031)	0.15

Notes: Standard errors clustered at the municipality level in parentheses, \*\*\* $p < 0.01$ , \*\* $p < 0.05$ , \* $p < 0.1$ . All RD estimates are obtained by local linear regression and optimal bandwidth as per Calonico, Cattaneo and Titiunik (2014a). All specifications include time and region fixed effects. The control variables included in all regressions are: % female government members, mayor's education, average years of education of the opposition members, and a binary variable for left-wing mayors. Revenues from fees and direct taxes are measured in euros per capita.

## Robustness checks

### Placebo tests

We conduct a series of placebo tests in order to increase confidence in the validity of our findings. The most relevant test is to examine the effect of the education of mayors on dependent variables lagged one period<sup>12</sup>. The estimates presented in Table 6 show that the education of mayors elected in certain year does not have any statistically significant effect on fiscal outcomes of the previous term as politicians do not have the capacity to influence such outcomes. This increases our confidence that the results presented in this chapter are not due to chance.

Table 6: Effect of mayors with university degrees on lagged fiscal outcomes

Variable	Coef.	SE
Total expenditures	-15.50	(17.22)
Personnel spending	1.63	(5.70)
Goods and services spending	-4.61	(6.43)
Capital spending	-14.09	(11.25)
Total revenues	-19.16	(17.44)
Capital transfers	-1.47	(8.36)
Current transfers	2.02	(6.24)
Financial revenues	-3.33	(3.94)
Taxes and fees	-13.74	(12.09)

Notes: Standard errors clustered at the municipality level in parentheses, \*\*\* $p < 0.01$ , \*\* $p < 0.05$ , \* $p < 0.1$ . All RD estimates are obtained by local linear regression and optimal bandwidth as per Calonico, Cattaneo and Titiunik (2014a). All specifications include time and region fixed effects. The dependent variables are expressed in euros per capita with one period lag (i.e., the education of governments during term  $t$  is regressed on fiscal outcomes of the previous term that this government cannot influence.).

The results confirm that the education of governments has no statistically significant effect either the revenues obtained through direct taxation or on financial expenditures.

<sup>12</sup>Electing a mayor with a university degree in 2003 is regressed on fiscal outcomes between 2000 and 2003, and in 2007 it is regressed on fiscal outcomes between 2004 and 2007.

## Who is driving these results?

We examine whether the effects of the education of mayors on economic outcomes and fiscal policy differ for left- and right-wing governments. To estimate "heterogeneous local average treatment effects" (HLATE) we interact the explanatory variable of interest (university educated mayor) with a dummy variable that equals one if the mayor is left-wing (Left). Table 7 shows these results. The estimates suggest that the role of education in affecting non-financial and current expenditures does not differ significantly for left- and right-wing governments, although we note that all interaction coefficients are negative. Column 3 shows that the preference of left-wing governments for more capital spending is lower when the mayor is more educated. Specifically, electing a mayor with a university degree reduces the large effect of having a left-wing government on spending by 35 euros per capita. The interaction term Education x Left is also significant for non-financial and capital expenditures, and indicate that the effect of having a left-wing mayor on revenues is decreased by 42 euros per capita when the mayor has a university degree. All in all, the results suggest that highly educated left-wing mayors choose more fiscally conservative fiscal policies.

Table 7: Heterogeneous effects of governments' education: left- and right-wing parties

	Non-financial expend.	Current expend.	Capital expend.	Non-financial rev.	Capital rev.
Education	-49.448 (60.023)	-6.133 (20.223)	-14.082 (30.701)	-23.048 (51.658)	14.859 (23.560)
Left	610.845 (367.438)*	9.510 (136.194)	478.887 (197.334)**	441.623** (316.019)*	251.832 (138.052)*
Education x Left	-44.466 (27.785)	-1.204 (10.359)	-35.293 (15.070)**	-41.615 (23.860)*	-17.577 (10.486)*

Notes: Standard errors clustered at the municipality level in parentheses, \*\*\*p<0.01, \*\*p<0.05, \*p<0.1. All RD estimates are obtained by local linear regression and optimal bandwidth as per Calonico, Cattaneo and Titiunik (2014a). All specifications include time and region fixed effects.

## Conclusions

Some scholars believe that educated citizens are more capable political leaders (Dal Bo and Finan, 2018). Recent empirical research echoes this elitist view and uses education as a proxy measure of leader quality. Using a detailed dataset about performance outcomes and fiscal policies at the local level, we find that highly educated leaders do not perform better on a variety of indicators. Instead, we find evidence supporting the claim that more educated politicians implement more fiscally conservative policies, both raising less revenue and spending less money. Our database allows us to pin down some aspects of how the actions of more and less educated politicians differ. We find that less educated governments are more expansionary, in the sense that they increase both revenues and spending, but we do not find that they use strategies that may be harmful in the long run. These results suggest that education should not be used as a proxy of leader quality.

Our substantive findings have broad-ranging implications. In sharp contrast to gender or ethnicity, the descriptive representation of less educated citizens has worsened over time in lock step with the

declining influence of trade unions. Our analyses suggest that the secular decline in the share of less educated politicians within left-wing parties can shift the policies of these parties in a more conservative economic direction (see also O’Grady, 2019). The result could be a mismatch between the preferences of the party leadership and their constituencies, leaving the door open for political entrepreneurs to appeal to the traditional supporters of the left. While we cannot provide direct evidence about the political consequences of the changing composition of politicians, it is noteworthy that the on-going realignment in advanced industrial democracies (Beramendi et al., 2015) is driven in part by changes in how more and less educated citizens vote. It is plausible that the increasingly elitist educational make-up of politicians is one reason, among others, why the traditional constituencies of center- left parties feel disconnected from mainstream parties and search for alternatives such as populist parties.

Our results are also relevant for research about the unequal responsiveness of politicians to the preferences of affluent citizens (Gilens and Page, 2014; Bartels, 2008; Giger, Rosset and Bernauer, 2012). A well-known finding is that when the preferences of citizens with a high or low socio-economic background differ, politicians are more responsive to the preferences of the rich. The mechanisms that generate unequal responsiveness are largely unexplored, though (see Becher and Stegmueller, in this volume). One possible mechanism suggested by our findings is the similarity in educational backgrounds between privileged citizens and elites. If educated citizens and elites share preferences and worldviews, it is unsurprising that when the preferences of the public diverge, elites side with people who are descriptively like them.

To be sure, our empirical analysis has limitations. We cannot tease out the relative effect of education, income, and occupation either. An important follow-up question is if different types of education and degrees affect preferences in different ways. For instance, the share of lawyers, engineers or economists in governments may have different effects on policies. Our work focuses on local elections in Spain in a specific time period and further research should establish if the results hold in other political arenas, geographic contexts, and time periods. Although we scrutinize a wide range of outcome measures, we lack some relevant measures of performance such as economic growth, which is not measured at the local level, or corruption. As is well known, RD estimates are internally valid, but they may not apply to contexts in which the margin of victory was not close.

In spite of these limitations, the result of our analyses support the view that the education of who is in government affects fiscal policies. According to Hanna Pitkin, having representatives with a similar distribution of politically relevant characteristics as the represented population is important not on its own sake but mainly because we “tend to assume that people’s characteristics are a guide to the actions they will take” Pitkin (1967, 89). Our results show that education does guide the actions of politicians and suggest that increasing the substantive representation of these disadvantaged citizens would change fiscal policies and make them less conservative.
